

The Task

We're going to give you a real spreadsheet we use internally — a clinic performance scoreboard (Scoreboard Test.xlsx). Your job is to write a Python script that reads this file and converts it into a **usable JSON file** without losing any data or headings.

The keyword is **usable**. We don't want a dump that's technically lossless but impossible to query. We want JSON that another developer (or an LLM, or a dashboard) could pick up and immediately make sense of.

Deliverables

1. `convert.py` — your script.
2. `requirements.txt`.
3. `output.json` — the result of running your script against Scoreboard Test.xlsx.
4. `README.md` — short. Tell us:
 - How to run it.
 - The JSON shape you chose, and *why*. A small example snippet helps.
 - What you decided to do about the messy bits (merged cells, spacer columns, formulas, etc.) and what trade-offs you made.
 - Anything you would have done with another two hours.
